Yu's Elite Education

Graphs

- ▶ In Computer Science we describe pairwise relationships as a “graph”
- ▶ Graphs are made up of two types of things:
 - ▶ Nodes (or vertices), which represent items
 - ▶ Edges, which represent relationships

Types of graphs

- ▶ Weighted vs. unweighted
 - ▶ Unweighted graphs have edges that either exist or don't exist, between each pair of nodes
 - ▶ Weighted graphs have a edges with a real-valued strength

Types of graphs

- ▶ Directed vs. undirected
 - ▶ Undirected graphs have edges that are symmetrical - $\text{edge}(a,b) = \text{edge}(b,a)$
 - ▶ Directed graphs have edges with different strengths in each direction

Representing graphs

- ▶ Two ways to store graphs in a computer:
 - ▶ Adjacency matrix: $\text{adj}[a][b]$ = edge between nodes a and b
 - ▶ If unweighted, $\text{adj}[a][b] = 0$ or 1
 - ▶ If undirected, $\text{adj}[a][b] = \text{adj}[b][a]$
 - ▶ Adjacency list: $\text{adj}[a]$ = set of a's neighbors (nodes with edges connected to a)
 - ▶ For weighted graph, also need to keep track of weights

Homework: Flight routes

- ▶ Download the time-table of flights:
[Departing] [Depart HHMM] [Arriving] [Arrive HHMM]
- ▶ Given a starting and ending city, compute the fastest set of flights to get from one to the other, assuming you need 60 minutes between flights
 - ▶ For example, Paris to Houston

Pagerank

- ▶ How do we determine the importance of individual nodes in a graph?
- ▶ Google became famous by coming up with a solution to this problem called “Pagerank”
- ▶ Basic idea: if a lot of important pages link to me, then I’m important!

Pagerank model

- ▶ Assume that people randomly click on links in webpages
- ▶ Where will most people end up?
- ▶ Example:
 - ▶ Page A has 4 links, 1 of which is to C
 - ▶ Page B has 2 links, 1 of which is to C
 - ▶ $PR(C) = PR(A)/4 + PR(B)/2$

Pagerank model

- ▶ One other tweak: assume that with probability $1-d$, people just jump to a random website
 - ▶ This avoids issues with pages that don't have links, and makes solving easier
- ▶ Final equation:

$$PR(A) = \frac{1-d}{N} + d \left(\frac{PR(B)}{L(B)} + \frac{PR(C)}{L(C)} + \frac{PR(D)}{L(D)} + \dots \right).$$

Calculating Pagerank

- ▶ Pagerank has a circular definition, so it is hard to calculate
- ▶ Can start with uniform Pageranks on all pages, then iterate Pagerank equations
- ▶ Let's code Pagerank for wikipedia

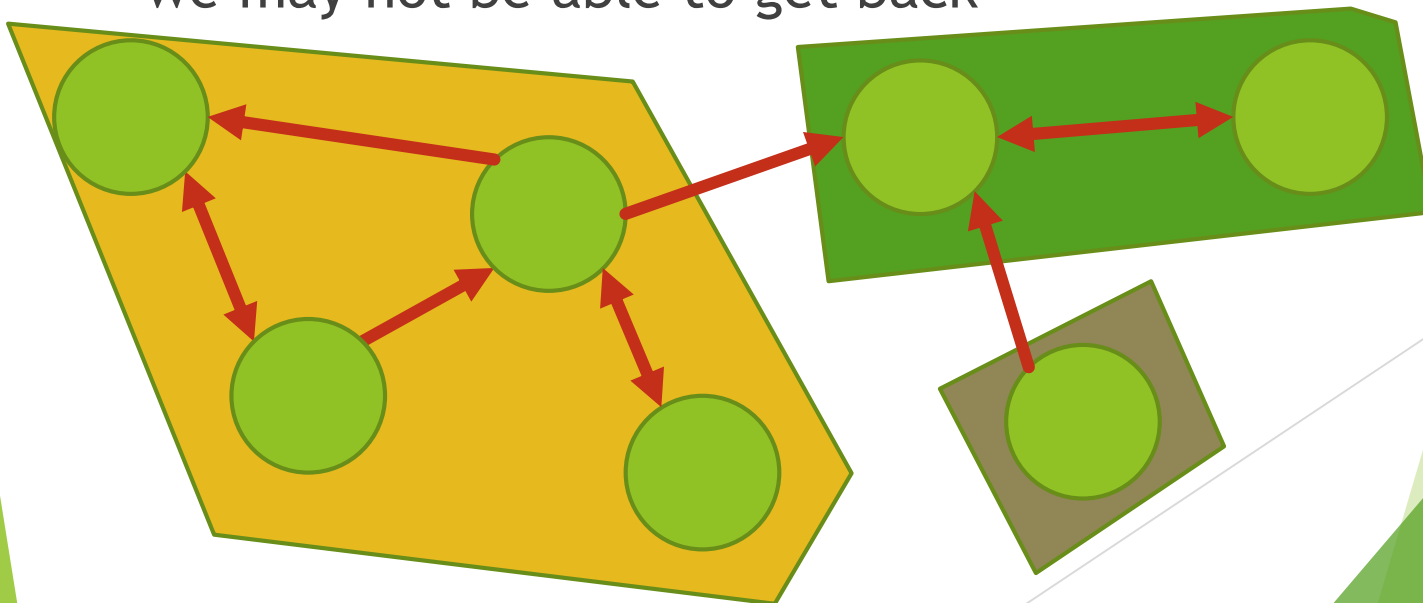

Strongly connected nodes

- ▶ In some directed graphs, we can move from every node to every other node
- ▶ We call this a “strongly connected” graph
- ▶ Which of these graphs are strongly connected?

Strongly connected components

- ▶ We can divide any graph into components that are strongly connected
- ▶ We can “move freely” within these components, but once we leave a component we may not be able to get back

Tarjan's algorithm for SCC

- ▶ Calculate 2 numbers at each node:
 - ▶ An index
 - ▶ Lowest index in my SCC
- ▶ Perform DFS, update lowest index when:
 - ▶ We find a new node
 - ▶ We find an old node in our SCC
- ▶ If $\text{index} == \text{lowest index after DFS}$, then create new SCC with this root

Tarjan's algorithm: Example

Tarjan's algorithm: Big O

- ▶ Equivalent to two depth-first traversals (one forward, one backward)
- ▶ DFS visits every node and every edge
- ▶ $O(N+E)$

Olympiad Example

▶ Grass Cownoisseur:

<http://usaco.org/index.php?page=viewproblem2&cpid=516>

Spanning tree

- ▶ For a connected, undirected graph, how many edges can we remove and still have a connected graph?

Minimum spanning tree

- ▶ If edges have weights, we want to select the spanning tree with the smallest total edge weight

Applications of minimum spanning tree

- ▶ Broadcast paths in the internet
- ▶ Planning a road system
- ▶ Hierarchical clustering
- ▶ Taxonomy and evolutionary biology

Prim's algorithm

- ▶ Surprisingly simple!
- ▶ Pick a random starting node
- ▶ Add minimum edge
- ▶ Keep adding smallest edge that connects to an unconnected node

Minimum spanning tree

Prim's Big O

- ▶ Depends on how we search for the next edge
- ▶ If we keep a heap of nodes with keys equal to their minimum edge, we will perform a decrease-key operation for each edge on a size N heap
- ▶ $O(E \log N)$

Homework

- ▶ Superbull:
<http://usaco.org/index.php?page=viewproblem2&cpid=531>
- ▶ Hint: if teams are nodes, tournament can be described by a spanning tree
