Yu's Elite Education

Last week recap

- ▶ Heaps
 - ▶ Heap structure and ordering
 - ▶ Adding elements
 - ▶ Removing elements
 - ▶ Using as priority queue
 - ▶ Heapsort

Problems with arrays

- ▶ Traditional arrays/lists store data in consecutive slots in memory
- ▶ Good: can easily calculate where element i can be found, as $(begin + i * datasize)$
- ▶ Bad: Inserting or deleting elements requires moving $O(N)$ elements (unless at end)
- ▶ Python example

Linked lists

- ▶ Linked lists do not store elements consecutively in memory
- ▶ Each element contains some data, and the memory address of the next element

Linked list

- ▶ <http://visualgo.net/list.html>

Big-O for linked lists

- ▶ Inserting or deleting a node (assuming we know memory address of insertion/deletion point) is $O(1)$ (vs. $O(n)$ for array)
- ▶ Indexing (finding n th piece of data) is $O(n)$ (vs. $O(1)$ for array)

Implementing linked list

- ▶ Node structure
 - ▶ Data field
 - ▶ Pointer to next node (NULL if end of list)
- ▶ Head pointer to first node

- ▶ Example in python

Reversing linked list

- ▶ Can we reverse all links in a linked list in a single pass?

Detecting loops in a linked list

- ▶ How can we check that our list doesn't have any loops?
- ▶ Traverse until end?
- ▶ Mark each node?
- ▶ Check node against entire list so far?
 - ▶ Works, but $O(N^2)$
- ▶ Floyd's tortoise and hare
 - ▶ <http://visualgo.net/cyclefinding.html>

Problems with one-directional links

- ▶ We can only iterate through the list in one direction
- ▶ Even if given the memory address of a node to delete, we'd have to iterate through the list to find the previous node
- ▶ Solution: Doubly-linked lists

Doubly-linked lists

- ▶ Every node contains data, and pointers to both previous and next nodes
- ▶ Have head and tail pointers to the front and back of the list
- ▶ Example in python (for show and insert)

Circular doubly-linked lists

- ▶ We can get rid of some of the special cases at the ends of the list by connecting the head and tail nodes to each other

Doubly Linked Circular list

- ▶ Example in python (for show and insert)

Stacks and Queues

- ▶ Linked lists are often used to implement two other data structures: stacks and queues
- ▶ Both allow us to add or remove one element at a time
- ▶ Queues: First-in-first-out (FIFO)
- ▶ Stacks: First-in-last-out (FILO)

Queues

- ▶ Uses of queues?
 - ▶ Website requests
 - ▶ Simulations or game engines
 - ▶ Expanding algorithms like Dijkstra's

Stacks

- ▶ Uses of stacks?
 - ▶ Recursive algorithms like mergesort
 - ▶ Backtracking algorithms like constraint satisfaction (e.g. Sudoku)
 - ▶ Compiling and running programs

Implementing Queue with linked list

- ▶ Why implement with linked list?
- ▶ Enqueue operation:
 - ▶ Add node at head
- ▶ Dequeue operation
 - ▶ Remove and return node at tail
- ▶ <http://visualgo.net/list.html>

Implementing Stack with linked list

- ▶ Why implement with linked list?
- ▶ Push operation:
 - ▶ Add node at head
- ▶ Pop operation:
 - ▶ Remove and return node at head
- ▶ <http://visualgo.net/list.html>

Stack example: Reverse Polish Notation

- ▶ Traditional math notation: requires knowing order of operations, using parentheses

$$7+(1+2)*5 = 22$$

- ▶ Reverse Polish notation avoids these issues by using a stack

$$7\ 1\ 2\ +\ 5\ *\ +$$

- ▶ Implement in python

Assignment: Median of sorted circularly linked list

- ▶ Sorted singly-linked circular list:

- ▶ Given a reference to some node, find median of the list
 - ▶ Note: need to handle all-equal special case
